# 1. Spindle bearings and high-speed spindle bearings

DLG - High-precision bearings

DLG-high-precision bearings are manufactured in single and double-row design as spindle bearings, high-speed spindle bearings and high precision cylindrical roller bearings.

# 1. Spindle bearings and high-speed spindle bearings

## 1. 1. General

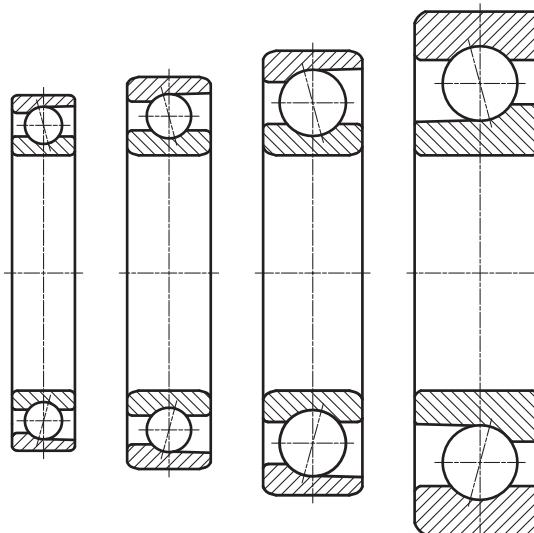

Spindle bearings are super precision angular contact bearings, which are used in machine tools, textile and printing machines and they are designed for carrying both axial and radial loads and used with pre-loads and most of the time in pairs with tandem and/or cross loading.

### 1. 1. 1. Spindle bearings

Spindle bearings are manufactured in series B719, B70, B72 and A73. Even different material combinations and designs are possible, as described in the following chapters. Special design of DAS LAGER precision spindle bearings are suitable for many applications where there is a demand for a high load-bearing capacity and at the same time high rotational speeds.

Fig. 1.1. Spindle bearing

B719.. B70.. B72.. A73..

Fig. 1.2. Series of high-speed spindle bearings

# 1. Spindle bearings and high-speed spindle bearings

## 1.1.2. High-speed spindle bearings

High-speed spindle bearings are identical, high-speed spindle bearings are identical to the B line of spindle bearings. They are distinguished in particular by their suitability for higher speeds, low friction and less heat development. High-speed spindle bearings are available in the series HS719 and HS70 as well as in different designs and material combinations.

Fig. 1.3. High-speed spindle bearing

## 1.2. Tolerances and standards

The main dimensions of the spindle bearings fulfill the general dimension plans for bearings according to DIN 616 (ISO 15). They are manufactured in dimensional series 19, 10, 02 and 03. The B719 and B70 series of bearings are designed in accordance with DIN 628-6.

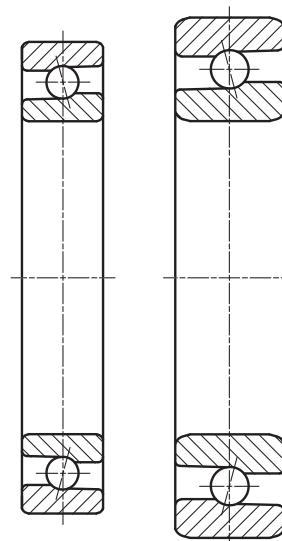

Fig. 1.4. Series of high-speed spindle bearings

## 1.3. Designs

To facilitate the installation of the cage and ensure the best-possible lubrication of the bearing during operation, one ring with a reduced rib diameter shall be used at least. The bearings are not dismountable.

Design	DLG-Series
B	B719, B70, B72
A	A73
HS	HS719, HS70

# 1. Spindle bearings and high-speed spindle bearings

## 1.4. Materials

### 1.4.1. Outer and inner rings, balls

Daslager Germany bearings are manufactured using vacuum degassed 100Cr6 chromium steel SAE 52100. The high degree of purity of the material ensures maximum reliability. The steel allows operating temperatures not exceeding 150°C without adversely affecting dimensional stability and hardness. Spindle bearings with ceramic balls and/or rolling bearing rings made of Cronidur 30 are used for special applications (see Section 4. Hybrid spindle bearings).

Fig. 1.4.1. Laminated phenolic resin cage

### 1.4.2. Cage

Spindle bearings generally used solid type one-window cages. They can be made of composite materials like phenolic resin reinforced with cotton fabric up to 100°C. For temperatures higher than 100°C brass cage is replaced.

Fig. 1.4.2. Brass cage

## 1.5. Contact angle

The contact angle  $\alpha$  is determined by the straight between the contact points ball/raceway and the radial plane. External loads are transferred from one bearing ring to another in the direction of the straights. To satisfy the different operating conditions, spindle bearings are usually manufactured with two different contact angles.

Contact angle	Code
15°	C
25°	E
40°	B

Increasing contact angle may increase the axial rigidity. However, the size of the contact angle influences the speed limit, i.e. the greater the contact angle, the lower the speed limit. The contact angle is determined by design and may change under operating conditions, such as different operating temperatures of the bearing rings and centrifugal forces at maximum rotational speeds, external forces.

## 2. Bearing data

### 2.1. Tolerances and tolerance classes

The following tolerance classes apply as a rule to the dimension and run-out tolerances of the spindle bearings:

Tolerance classes	Standards
P4 and P2	according to DIN 620-2
P4S	according to DIN 628-6 (Standard)
P2S	according to DLG in-house standard

To ensure a wide variety of applications and thus a high quality in terms of use, spindle bearings are normally manufactured at DLG for the tolerance class P4S, i.e. the connection parameters of the bearings have a P4 quality and important parameters for running characteristics, such as radial run-out, have P2 tolerances.

## 2. Bearing data

The width tolerance $\Delta_{\text{Cs}}$ is identical to $\Delta_{\text{Bs}}$ for the associated inner ring.												

## 2. Bearing data

### Tolerance class P2S

Tolerances of tolerance class P2 that are further restricted are established as in-house tolerance class P2S.

These bearings satisfy the most stringent precision requirements and are suited for maximum rotational speeds.

Inner ring(Dimensions in mm)									
Nominal bore diameter	over to	0 10	10 18	18 30	30 50	50 80	80 120	120 150	
Tolerance class P2S (Tolerances in $\mu\text{m}$ )									
Deviation	$\Delta_{ds}, \Delta_{dmp}$	0 -2	0 -2	0 -2	0 -2,5	0 -4	0 -5	0 -6	
Roundness $V_{dp}/2$	Row 8 • 9	1	1	1	1,5	2	2	2,5	
	Row 0 • 2	1	1	1,5	1,5	1,5	2	2,5	
Width deviation	$\Delta_{Bs}$	0 -25	0 -25	0 -25	0 -25	0 -25	0 -50	0 -50	
Width variation	$V_{Bs}$	1	1	1	1,3	1,3	2	2	
Radial runout	$K_{ia}$	1,3	1,3	1,5	1,5	2	2	2,5	
Variation in inclination of outside cylindrical surface to bore	$S_d$	1,3	1,3	1,3	1,3	1,3	2	2	
Assembled bearing inner ring face runout with raceway (axial runout)	$S_{ia}$	1,3	1,3	2	2	2	2	2,5	
Outer ring(Dimensions in mm)									
Nominal outside diameter	over to	10 18	18 30	30 50	50 80	80 120	120 150	150 180	
Tolerance class P2S (Tolerances in $\mu\text{m}$ )									
Deviation	$\Delta_{dmp}, \Delta_{ds}$	0 -2,5	0 -3,5	0 -3,5	0 -3,5	0 -4	0 -4	0 -6	
Roundness $V_{dp}/2$	Row 8 • 9	1	2	2	2	2	2	3	
	Row 0 • 2	1	1,5	1,5	1,5	2	2	2,5	
Width variation	$V_{Cs}$	1	1	1	1,3	2	2	2	
Radial runout	$K_{ea}$	1,5	2	2	2,5	3	3	3,5	
Variation in inclination of outside cylindrical surface to outer ring side face	$S_D$	1,3	1,3	1,3	1,3	2,5	2,5	2,5	
Assembled bearing outer ring face runout with raceway (axial runout)	$S_{ea}$	1,5	2	2	3	4	4	4	

The width tolerance  $\Delta_{Cs}$  is identical to  $\Delta_{Bs}$  for the associated inner ring.

## 2. Bearing data

### 2.2. Dimension groups for spindle bearings

In case of spindle bearings, the dimension tolerances with regard to bore and outer diameter are divided into three ranges. The middle variation of the range is written down as actual value in  $\mu\text{m}$  on the outer ring (e.g.  $< -3 >$ ) or inner ring (e.g.  $< -1 >$ ).

### 2.3. Speeds of Rotation

Spindle bearings are especially well suited for high rotational speeds. Factors that influence the rotational speed:

- Contact angle: The speed limit decreases with the increasing contact angle.
- Preload: The permissible speed decreases with the increasing preload.
- Operating temperatures: special consideration of heat dissipation
- Installation layout: The max. speed is attained with the installation of a single bearing. In case of bearing sets consisting of two or more bearings, the speed reduces accordingly. (Section 7.4.)
- Precise machining of the bearing seats
- Cage type: low cage weight means less imbalance; the guidance at the rib diameter of the outer ring also allows the cage to center itself.
- Lubrication: when lubricating with grease, only approx. 65% of the achieved speed of oil lubrication
- Dimensional series: The smaller the bearing's cross-section, the better it is suited for high speeds.
- Precision: The speed limit increases with the increasing precision.

Correction factors, with which the prescribed speeds are to be multiplied for the spindle bearings:

Bearing properties	Correction factor
<b>Accuracy</b>	
P4	0,9
P4S	1
P2	1,1
P2S	1,15
<b>Contact angle</b>	
15°	1
25°	0,9
<b>Lubricant</b>	
oil	1
grease	0,65

These values are guidelines, applicable to a fixed preloading under optimal working conditions like installation tolerances, operating temperatures, lubrication, etc. The dynamic balancing level is important for ensuring good movement.

## 2. Bearing data

### 2.4. Operating temperature

DLG spindle bearings are heat treated such that they are dimensionally stable up to an operating temperature of 150°C. The operating temperatures of the cages, the bearing seal and the lubricant can further restrict the upper operating temperature of the bearing.

Part	Upper temperature range
Roller bearing rings	150°C
Laminated phenolic resin cage (standard)	100°C
Brass cage	150°C
PEEK cage	approx. 260°C (up to 150°C without performance restrictions)
Sealing discs of NBR (2RSD)	110°C
Lubricant grease L75 (standard)	120°C

If it is possible, the bearing temperature at the outer ring should not exceed 80°C. If applicable, the bearings are to be cooled, e.g., by means of the housing cooling system or circulating oil lubrication.

### 2.5. Noise

The noise level of the spindle bearings is a sign of their quality and the running characteristics of the bearings. Since bearing noise is caused by any existing irregularities, undulation and roughness, particular attention is placed on ensuring maximum quality especially with regard to the above characteristics during production. Appropriate measuring technology is used to support this process. All bearings undergo full quality control testing with regard to noise with the aid of specific noise testing equipment, ensuring that we only deliver bearings that satisfy high standards. This test also provides feedback relating to the cleanliness of the bearings.

## 3. Universal bearings, bearing sets

### 3.1. „U“ universal bearings

DLG production portfolio also includes bearings with universally matched designs (UL, UM, US). Universal bearings „U“ are defined such that both sides of the inner and outer ring are properly aligned when exposed to a predefined axial force (preload force). In real terms, this means that if the inner rings of two identical spindle bearings are axially loaded (O-configuration), the result is precisely the preload force indicated by the bearing manufacturer:

- light (UL)
- medium(UM)
- heavy(US).

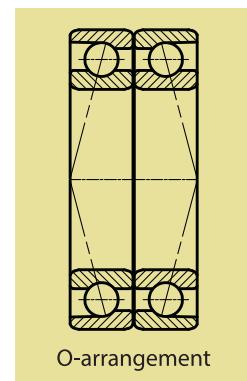

The X-arrangement behaves in a similar fashion, whereas the outer rings of both bearings are axially tensioned here. Spindle bearings in universal design (same size and same design) can be installed in any arrangement. A uniform load distribution is best achieved with DLG bearing sets that are already matched to one another during production. DLG moreover offers the following options for enabling a simple warehousing and ensuring a high flexibility:

- Two-piece sets, e.g. with the suffix DUL. That stands for a dublex bearing pair, where the dimensions of the bore and cladding diameter matched to one another and can be installed both in O (DB), X (DF) or T (DT) configuration. The evenness thus imparted is especially important for high speeds and high level of accuracy and are recommended by DLG.
- Three-piece sets, e.g. with the suffix TUL along the lines of the two-piece sets.
- Four-piece sets, e.g. with the suffix QUL along the lines of the two-piece sets.

### 3.2. Bearing arrangements

#### 3.2.1. O-arrangement (DB suffix)

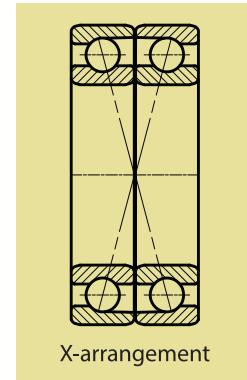

The pressure lines drift apart in the direction of the bearing axis. That results in a large pitch on the bearing axis. A very rigid bearing against tilting moments is achieved by this arrangement and the bearing absorbs axial forces in both directions.

O-arrangement

#### 3.2.2. X-arrangement (DF suffix)

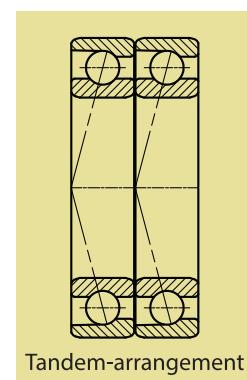

The pressure lines merge in the direction of the bearing axis. That results in a small pitch on the bearing axis. The tilting rigidity is lesser compared to 3.2.1. The configuration is less sensitive to misalignment. The bearing pressure and elasticity is along the lines of the O configuration.

X-arrangement

#### 3.2.3. Tandem-arrangement (DF suffix)

Both paired bearings are arranged parallel in the direction of the load, whereas a greater axial load than with individual bearings is possible in the direction of the load. Each of the two bearings accommodates an almost equal share of the axial load. It must be taken into account that the tandem pair must be preloaded in any case against a third bearing.

Tandem-arrangement

### 3. Universal bearings, bearing sets

#### 3.2.4. Multiple arrangement

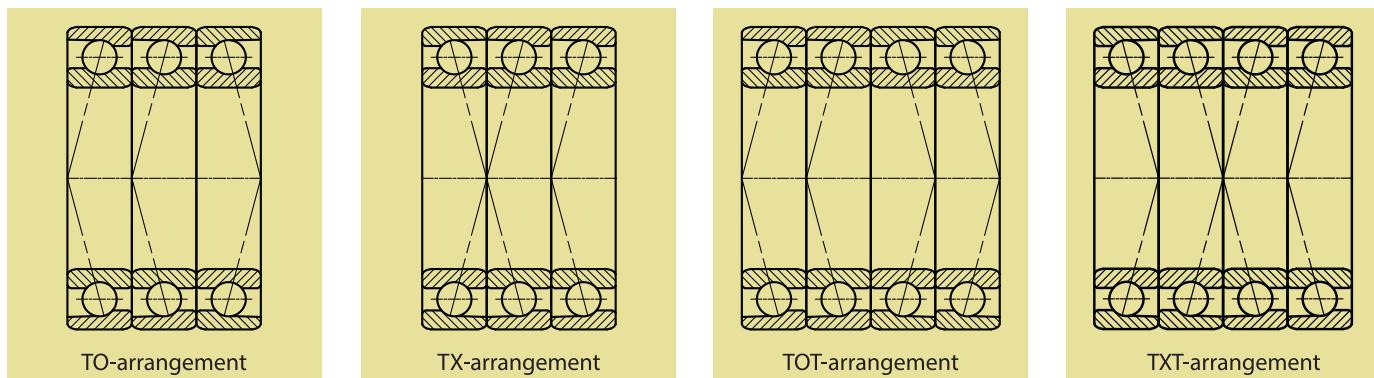

In case of greater loads or demands for high rigidity, 3 or 4 or even 5 bearings in exceptional cases are assembled into sets and installed. Bearings matched in this manner are manufactured, marked and packaged at DLG either in pairs or sets. These bearings have the same measurements in terms of bore and outer diameter.

##### 3.2.4.1. TO-arrangement (TBT suffix) and TX-arrangement (TFT suffix)

Both of these arrangements are used like the tandem arrangement to accommodate high axial loads in one direction. The additional third bearing is used for counter guidance and makes the multiple configuration a fixed bearing.

##### 3.2.4.2. TOT-arrangement (QBC suffix) and TXT-arrangement (QFC suffix)

Both arrangements are used as fixed bearings for high radial loads and high axial loads. These arrangements result in a very high rigidity. It is not appropriate to install more than three bearings directly next to one another, since heat dissipation would be worse and the supply of lubricant to all bearings more difficult. That's why spacer rings are to be used here.

## 3. Universal bearings, bearing sets

### 3.3. Distance rings

Installing spacer rings (an inner and an outer ring respectively) between the matched bearings should result in the following:

- The bearing pitch with X and O configuration is increased.
  - Lubrication is improved, i.e. the supply of oil to every bearing is possible and there is a grease reserve in case of grease lubrication.
  - The resulting frictional heat can be dissipated more readily.
  - The use of spacer rings can change the preloading for the X and/or O configuration. In real terms, that means: the inner spacer ring has a flimsier design than the outer ring and the preloading decreases with the X configuration or it increases with the O configuration.
  - The necessary measurement variances are available upon request.

During the production of spacer rings, particular attention must be placed on ensuring plane parallelism and evenness. Both spacer rings are to be surface-ground in a single step, if possible.

Tolerance class	P0, P6, P5, P4	P2
Difference in the widths of the inner an outer distance rings	3,0	2,0
Variation of width	2,5	1,3
Axial run-out	2,5	1,3

## 4. Hybrid spindle bearings

Hybrid spindle bearings are bearings with races consisting of bearing steel and balls made of a ceramic material (silicon nitride Si<sub>3</sub>N<sub>4</sub>) of maximum homogeneity and hardness. Ceramic balls are moreover lighter than steel balls. That results in less centrifugal forces and thus less friction. They are insulated with regard to electricity and they are not magnetic. They are also resistant to corrosion. These bearings are specifically designed as heavy-duty bearings for machine tool spindles and offer the prerequisites for a high productive capacity. Based on the positive characteristics of ceramics, the hybrid bearings are characterized by a considerably lower friction during operation and thus offer the following advantages compared to bearings with steel balls:

- approx. 20% higher rotational speeds
- better operation after lubrication-system failure
- higher stiffness
- less vibration
- less noise
- more favorable acceleration and deceleration performance

Hybrid bearings were originally used specifically for high speed applications. Based on nearly same service life as bearings with steel balls they are also used in all other series of bearings.

Fig. 4.1. Hybrid spindle bearing

## 5. Sealed spindle bearings

Spindle bearings of sealed design (2RSD) are also included in the DLG production portfolio as in the bearing tables. The greasing of these maintenance-free bearings is coordinated such that the bearings have a low temperature while running at high speeds over long periods. Thanks to their relatively simple installation, lubrication and maintenance, they are the optimum solution for customers with long useful life requirements.

Bearings of same size and series in unsealed design can be replaced with similar bearings in sealed design.

Fig. 5.1. Spindle bearing in 2RSD design

## 6. Spindle bearing with direct lubrication

In case of applications with oil-based minimum quantity lubrication, the lubricant can be directly supplied to the point of contact (ball/race) thanks to these designs. The DLR design features a circumferential lubrication groove and hole approx. Ø 0.5 mm at outer ring. Two radial grooves with installed O rings made of NBR (standard) ensure an optimum seal to the spindle housing. The user is responsible for making the feed hole in the appropriate location on the housing.

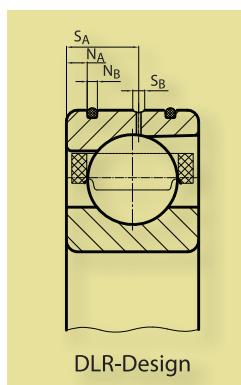

Fig. 6.1. Spindle bearing in DLR design

# 7. Bearing design calculation

## 7.1. General

The design calculation for the basic load rating and service life of bearings is based on the standard DIN ISO 76 (Static Load Ratings) and DIN ISO 281 (Dynamic Load Ratings and Nominal Rating Life). These standards describe comprehensive design calculations. As a result, we will only focus on the fundamental design calculations below. These design calculations are used to provide an approximate assessment of a bearing.

More in-depth bearing evaluations are possible by calculating the Hertzian contact pressure between rolling elements and race while taking into account the actual lubrication conditions with the aid of specific calculation programs. Please contact our Design department in this regard.

## 7.2. Nominal Rating Life

The bearing's rating life is indicated by the number of revolutions or hours of running until the bearing shows the first signs of damage. The most frequent causes are wear and tear, seizing up, and overheating due to over-loading (mechanical and thermal) as well as material fatigue. The most frequent cause for failure in high-speed applications is overheating followed by the bearing seizing up. According to DIN ISO 281, the nominal rating life of a group of same model spindle bearings with the same contact angle is calculated as follows:

$L_{10} = \left( \frac{K \cdot C_r}{P_r} \right)^3$	in millions of revolutions
$L_{10h} = \frac{L_{10} \cdot 10^6}{60 \cdot n}$	in hours
$L_{10}$	Nominal rating life in millions of revolutions with 10% failure probability
$L_{10h}$	Nominal rating life in hours with 10% failure probability
$C_r$	Dynamic radial load rating in N
$K$	Correction factor, depends on the number of spindle bearings „i“: $K=i^{0.7}$
$P_r$	Dynamic equivalent radial loading in N
$F_a$	Axial load of bearing group in N
$F_r$	Radial load of bearing group in N
$n$	Revolutions in $\text{min}^{-1}$

# 7. Bearing design calculation

## 7.3. Equivalent dynamic loading

If bearing are exposed to radial and axial loading at the same time, these loads are compiled to an equivalent load for the purpose of calculating the rating life. The equivalent dynamic loading is calculated as follows:

$$P_r = X * F_r + Y * F_a \text{ (in N)}$$

Both factors X and Y depend on the ratio of the axial-to-radial load  $F_a/F_r$  while compared to the bearing-specific factor e.

Individual bearings or tandem-arrangement			$F_a / F_r \leq e$		$F_a / F_r > e$	
a	$F_a / (i^* C_O)$	e	X	Y	X	Y
15°	0,015	0,38	1	0	0,44	1,47
15°	0,029	0,4	1	0	0,44	1,4
15°	0,058	0,43	1	0	0,44	1,3
15°	0,087	0,46	1	0	0,44	1,23
15°	0,12	0,47	1	0	0,44	1,19
15°	0,17	0,5	1	0	0,44	1,12
15°	0,29	0,55	1	0	0,44	1,02
15°	0,44	0,56	1	0	0,44	1,0
15°	0,58	0,56	1	0	0,44	1,0
25°	-	0,68	1	0	0,41	0,87

Bearings installed in X- or O- arrangement			$F_a / F_r \leq e$		$F_a / F_r > e$	
a	$F_a / (i^* C_O)$	e	X	Y	X	Y
15°	0,015	0,38	1	1,65	0,72	2,39
15°	0,029	0,4	1	1,57	0,72	2,28
15°	0,058	0,43	1	1,46	0,72	2,11
15°	0,087	0,46	1	1,38	0,72	2,0
15°	0,12	0,47	1	1,34	0,72	1,93
15°	0,17	0,5	1	1,26	0,72	1,82
15°	0,29	0,55	1	1,14	0,72	1,66
15°	0,44	0,56	1	1,12	0,72	1,63
15°	0,58	0,56	1	1,12	0,72	1,63
25°	-	0,68	1	0,92	0,67	1,41

## 7.4. Calculation of speed limit

The number of bearings, their arrangement, loading (air or preloading), outer load and lubrication on the one hand and heat dissipation on the other hand are decisive factors for speed. The speeds indicated in the bearing tables are to be considered as guidelines and may vary in both directions depending on the above conditions. The cited speeds are not attained in case of installation of rigidly preloaded bearings as well as pairs and sets of bearings. The following table outlines the corresponding factor for calculating the appropriate speed. This results in any case in a speed reduction.

Rotational speed reduction for spindle bearing sets ( $n \cdot f_r$ )					
Bearing spacing large	Factor $f_r$				
	Bearing preload				
	light	medium	heavy/high	S	
Ø	Q	0,85	0,75	0,50	
ØØ	QQ	0,80	0,70	0,50	
ØØØ	QQ	0,75	0,65	0,45	
Fixed bearing	Movable bearing	L	M	S	
ØQ	ØQ	0,75	0,60	0,35	
QØ	QØ	0,65	0,50	0,30	
ØØQ	ØQ	0,65	0,50	0,30	
ØØQQ	ØQ	0,72	0,57	0,37	
ØØØQ	ØQ	0,54	0,40	0,37	

**n corresponds to the rotational speed according to the catalogue**

## 7. Bearing design calculation

### 7.5. Suspension and stiffness

Thanks to bearings free of clearance, a very high running accuracy is achieved even when subject to varying loads. The required stiffness and the type of loading determine how the bearings are arranged and preloaded. Arranging bearings in sets significantly increases the stiffness. The values indicated in the bearing tables for axial stiffness are for bearing pairs in O or X arrangement. Bearing sets with three or more bearings yield higher values for axial stiffness. The radial stiffness can be calculated with the aid of a factor from the axial stiffness as follows:

$$S_r \approx 6 * S_a \text{ für } \alpha = 15^\circ$$

$$S_r \approx 2 * S_a \text{ für } \alpha = 25^\circ$$

If more than two bearings are combined into sets, the axial stiffness is increased. The following table illustrates the calculation of this stiffness for concentrically acting axial force.

Combination	$S_a$	$K_{aE}$ (lifting force) $\alpha = 15^\circ$ und $\alpha = 25^\circ$
	N/ $\mu$ m	N
DB	$S_a$	$3 * F_V$
TBT	$1,64 * S_a$	$6 * F_V$
QBC	$2 * S_a$	$6 * F_V$
QBT	$2,24 * S_a$	$9 * F_V$

### 7.6. Load-bearing capacity

The dynamic load rating for bearing sets with bearings matched in any configuration is obtained by multiplying the load rating C for the individual bearing with

1,62 for sets with 2 bearings

2,16 for sets with 3 bearings

2,64 for sets with 4 bearings

3,09 for sets with 5 bearings

The static load rating is obtained by multiplying the tablecited value C0 with 2 or 3, 4 or 5.

## 7. Bearing design calculation

### 7.7. Preloading

The predefined axial forces (preload forces) are: light (L), medium (M) and heavy (S). The preload forces indicated in the bearing tables apply to the axial pretensioning of bearing pairs (in O- or X- arrangement). In case of a combination of more than two bearings, the preloading values are to be multiplied as follows.

Combination	Factor
DB, DF	1
TBT, TFT	1,35
QBC, QFT	1,6
QBC, QFC	2

Preloading refers to a constant axial loading that is applied to the bearing. It has a major impact on

- the attainable speeds
- the stiffness
- the permissible loads

The pretensioning should only be as large as is necessary. The standard design has a light pretensioning (UL), which may be generated firmly (bearings pretensioned against one another) or elastically (with springs).

Fixed preloading (axially mounted):

- thermal effects may increase considerably – major impact on max. attainable speed.

Elastic preloading (springs):

- thermal effect is eliminated for the most part with springs – max. attainable speeds are hardly influenced. In case of high speeds, a minimum preloading is necessary. This depends on the outer axial load. The lifting force is the limit of the outer axial load, above which the impact of the preloading is raised in case of disburdened ball valves.

The related effects include:

- Balls and races are no longer constantly in contact
- Sliding friction increases
- Wear increases
- Useful life decreases

## 8. Installation tolerances of spindle bearings

### 8.1. Machining tolerances of the parts surrounding the bearings

The high capacity of spindle bearings is only guaranteed if the accuracy of the relevant adjacent parts are adapted according to the precision of bearings. This is necessary since the rings of the spindle bearings, especially the dimensional series with low cross-sections, adapt to the shape of the shaft or the housing bore. This can result in defects in form and misalignment, which cause increased operating temperatures. The higher the required speeds and levels of precision are for the bearing, the more these faults become evident. The average roughness  $R_a$  of the bearing seats must be complied with in order to ensure that the corresponding fit only varies very slightly in case of installation (smoothing of surfaces).

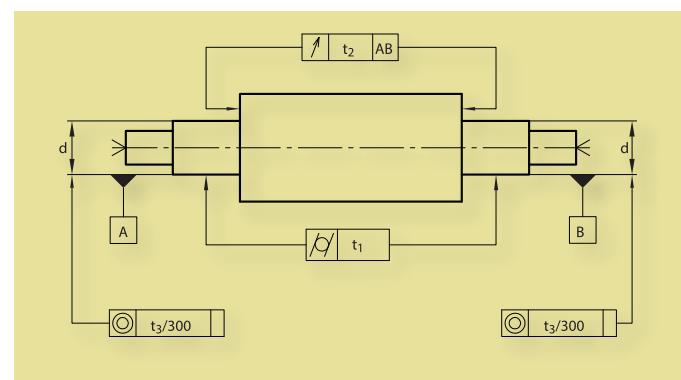

Fig. 8.1. Machining of shaft

# 9. Installation

## 9.1. Preparation of installation

Super precision bearings fulfill the stringent requirements on cleanliness and precision. The bearings should be installed with the utmost care. Make sure that they are installed in a room that is as clean as possible and free of dust with regulated temperature. Prior to installing the bearings, the dimensional accuracy of the connecting parts must be checked. Only provide and use tools that are suited for installation. In case of bearing sets, preferably combine bearings that have the same diameter grades (actual values). Only open the bearing packages right before the installation. Remove excessive anti-corrosion oil with the aid of a clean lint-free cloth.

## 9.3. Bearing installation

### 9.3.1. Installation with press

Apply a thin film of oil to the shaft. During pressing, no forces may be transferred via the rolling elements. Press the bearing on evenly over the inner ring up to the shaft shoulder with the aid of a suitable installation tool. Avoid a canting of the rings.

### 9.2. Greasing of bearings

In case of greasing and incompatibility of the anti-corrosion oil with the provided grease, the bearings are to be washed using a low-viscosity oil or kerosene and dry. Afterwards, grease the bearings with the recommended amount of grease with the aid of syringe or spatula in the same amount between the rolling elements, preferably the inner race, and then turn by hand to ensure that the grease is distributed evenly in the bearing. (The information on recommended amount of grease can be found in Section 23.2.3. Amount of grease.)

### 9.3.2. Installation with high bearing temperature

Heating up the inner ring, e.g. by using an inductive heating device simplifies the installation of the inner rings. The greater the overlap of the inner race fit, the greater the temperature must be. This may not exceed 120°C, however. Subsequent temperature differences in Kelvin (K) are recommended:

Shaft tolerance/ Bore	j5	k5	m5	n6	p6	r5
d < 80	50	60	70	80	100	100
80 < d <= 180	40	40	45	55	65	75
180 < d <= 315	30	35	40	45	50	60
315 < d <= 500	30	30	35	40	45	55

After cooling the inner ring, press on the shaft should again and check the axial and radial running accuracy.

# 9. Installation

## 9.4. Bearing securing

### 9.4.1. Fastening with precision nuts

The inner rings are tensioned with a lock nut. The recommended tightening torque creates the clamping force that safely overcomes the preloading of the bearings in case of an O or multiple bearing arrangement. To avoid any signs of setting, first tighten the nuts with two to three times the tightening torque, then loosen and tighten the nuts to the recommended tightening torque.

BKZ	Bore number
d	Bore diameter in mm
Ma	Tightening torque in Nm
Fz	Resulting clamping force in kN

Recommended tightening torques for axial tension of the bearing inner rings with the aid of nut

### 9.4.2. Fastening with housing cover

Especially in case of an X arrangement and fixed bearing, the outer rings are usually preloaded with the housing cover. Since the width tolerance especially of the adjusted spindle bearings is relatively large, the cover must be adjusted in particular. Prior to tightening the cover screws, it is necessary to ensure that the following gap is maintained between the cover and the housing.

Bearing bore	Housing cover gap a
< = 100 mm	0,01 to 0,03 mm
> 100 mm	0,02 to 0,04 mm

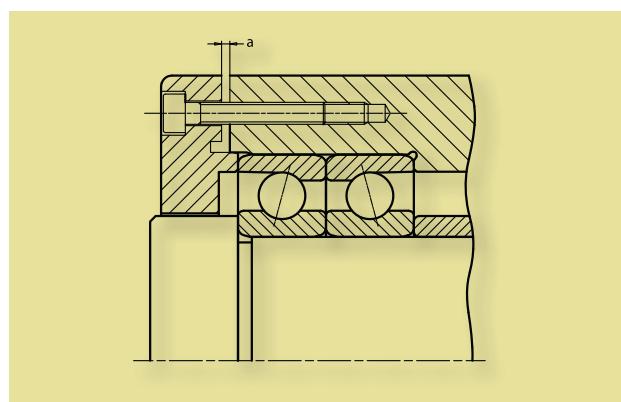

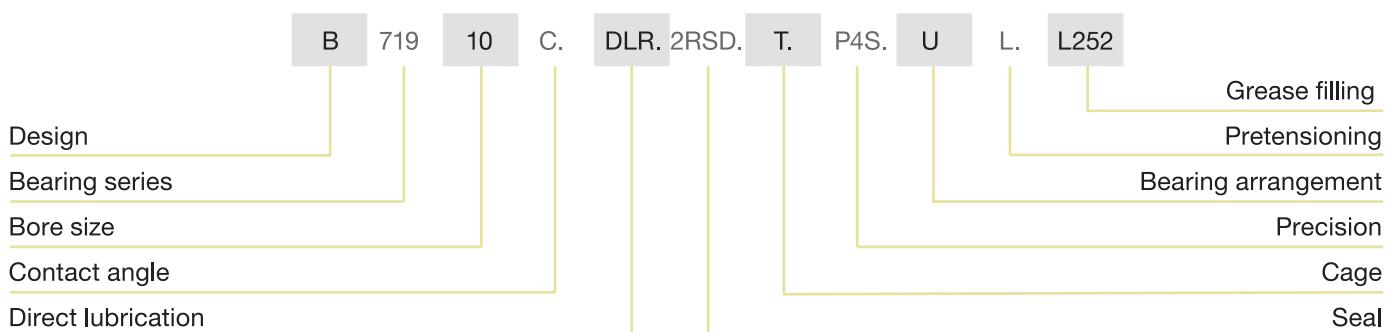

Fig. 9.1. Fastening with housing cover

# 10. Bearing labelling

## 10.1. Labelling schema for spindle bearings

Design	
B	Standard with steel balls
HCB	Standard with ceramic balls
XCB	Standard with ceramic balls, rolling bearing rings made of Cronidur 30
A	Standard with steel balls
HS	High speed bearings with steel balls
HC	High speed bearings with ceramic balls
XC	High speed bearings with ceramic balls, rolling bearing rings made of Cronidur 30
Bearing series	
719	light series
70	medium series
72	medium-heavy series
73	heavy series
Bore size	
02	15 mm
03	17 mm
04	4*5 = 20 mm
05	5*5 = 25 mm
06	6*5 = 30 mm (etc.)
Contact angle	
C	15°
E	25°
Direct lubrication	
DLR	Circumferential groove and radial feed hole and two radial grooves with O rings at the outer diameter

Seal	
2RSD	sealed and greased on both sides
RSDO	sealed on one side, disc on the side of the large outer ring/rib diameter, ungreased
RSDX	sealed on one side, disc on the side of the small outer ring/rib diameter, ungreased
Cage	
T	Window cage made of laminated fabric, guide on outer ring
MPA	Window cage made of brass, guide on outer ring
ENPA	Window cage made of PEEK, guide on outer ring
Precision	
P4S	Standard design according to in-house standard (run-out tolerances after P2) with additionally restricted bore and outer diameter tolerance of the respective tolerance class
K5	tolerance of the respective tolerance class
P4	as per DIN 620-2
P2	as per DIN 620-2
P2S	Tolerance as per in-house standard better than P2
Bearing arrangement	
U	Individual bearing suited for any configuration, designation of bearing sets in Section 3.2.
Pretensioning	
L	light
M	medium
S	heavy
Grease filling	
-	without
-	for sealed bearings by default L75; or L252 as alternative
L75	L75 Klüberspeed Bf 72-22 from Klüber
L252	L252 Turmogrease Highspeed from Lubcon

# 13. High-precision cylindrical roller bearings

## 13.1. General

High-precision cylindrical roller bearings are manufactured in single and double-row design and represent ideal floating bearings. They are distinguished by a high radial stiffness. Besides use as floating bearing, they are also used where radially stiff, stable and high-precision bearings are required. The standard version of the bearings has a tapered bore for precise adjustment of radial play (taper 1:12). The desired radial clearance or radial pretensioning is thus adjusted by an axial shifting on the tapered shaft seat.

There are moreover cylindrical roller bearings with cylindrical bore. The order designation does not include the „K“ (e.g. NN3012M.HP).

The main dimensions correspond with the general rolling bearing dimensional plans as per DIN 616 (ISO 15).

Fig. 13.1. single-row high-precision cylindrical roller bearing

## 13.2. Heat treatment

The high-precision cylindrical roller bearings are heat-treated such that they can be used with operating temperatures of up to 150°C. Bearings with an outer diameter greater than 120mm are dimensionally stable up to 200°C.

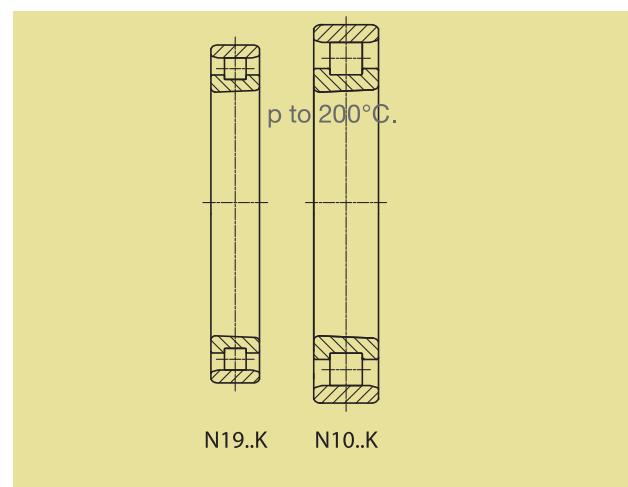

Fig. 13.2. series of single-row high-precision cylindrical roller bearing

## 13.3. Designs

Single-row high-precision cylindrical roller bearings are produced in series N19 and N10. In case of design N, the inner ring has two ribs and the outer ring is without a rib.

Double-row high-precision cylindrical roller bearings are produced in series NN30 and NNU49 in accordance with DIN 5412-4. The NN designation implies that the bearing is

## 13. High-precision cylindrical roller bearings

Double-row, the inner ring has three ribs, while the outer ring has not ribs. In case of design NNU, the outer ring has three ribs, while the inner ring is without a rib.

Upon request, the outer ring can be delivered with a lubrication groove and at least three lubrication holes. In this regard, an „S“ is indicated in the order designation after the code (e.g. NN3012K.S.M.HP). As a result, the lubricant can be supplied directly between the rollers.

Fig. 13.4. double-row high-precision cylindrical roller bearing, series NNU49

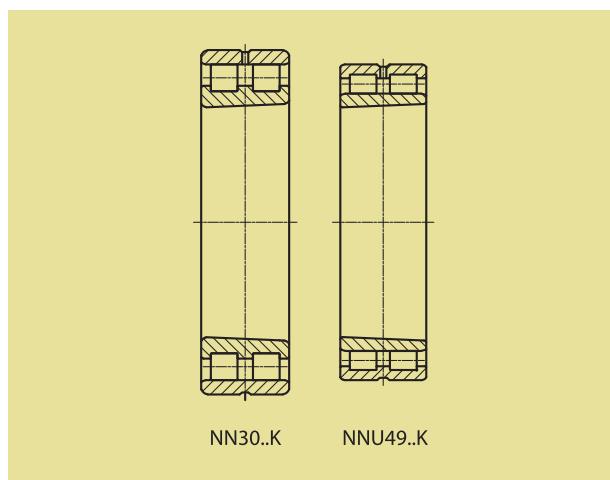

Fig. 13.5. series of double-row high-precision cylindrical roller bearing

Fig. 13.3. double-row high-precision cylindrical roller bearing, series NN30

## 13. High-precision cylindrical roller bearings

### 13.4. Hybrid cylindrical roller bearings

The hybrid cylindrical roller bearings of the HCN10 series have ceramic cylindrical rollers.

Their use significantly improves characteristics in terms of friction and wear and tear. This results in decreased lubricant stress and lower temperatures. For this reason, higher speeds are also permissible.

Fig. 13.4. Hybrid cylindrical roller bearing

# 13. High-precision cylindrical roller bearings

## 13.5. Materials

In the standard design, the bearing rings and cylindrical rollers of the high-precision cylindrical roller bearings are made of vacuum degassed chromium steel 100Cr6 or 100CrMnSi6-4 in case of larger dimensions. The high-precision cylindrical roller bearings usually have a solid brass cage guided by rolling elements. Upon request, PEEK cages can also be used for single-row high-precision cylindrical roller bearings.

Fig. 13.6. brass cage, single-row

Fig. 13.7. PEEK cage, single-row

Fig. 13.8. brass cage, double-row

## 14. Tolerances and tolerance classes

### Tolerance class HP

The cylindrical roller bearings have a high precision due to their use and thus exhibit a tolerance class HP. It satisfies the tolerance class SP according to DIN 5412 4. Bearings with UP tolerance class can be manufactured for applications with

even greater demands according to DIN5412-4. Upon request, the bearings are also available in other tolerance classes.

The width tolerances  $\Delta C_s$  and  $V_{C_s}$  are identical to  $\Delta B_s$  and  $V_{B_s}$  for the associated inner ring.

# 15. Bearing clearance

## Radial clearance of single-row and double-row high-precision cylindrical roller bearings C1

The bearings have a standard radial clearance C1 (smaller than normal play CN). Based on this bearing clearance, the bearings are not interchangeable, i.e. the outer rings cannot be switched out between the individual

bearings as is the case, e.g., with single-row cylindrical roller bearings. Both C1 and NA (for not interchangeable) is not indicated. Other radial clearances are available upon request.

# 16. Installation tolerances for cylindrical roller bearings

## 16.1. Machining tolerances of the parts surrounding the bearings

The high capacity of cylindrical roller bearings is only guaranteed if the accuracy of the relevant adjacent parts are adapted according to the precision of bearings. This is necessary since the rings of the cylindrical roller bearings adapt to the shape of the shaft or the housing bore. This can result in defects in form and misalignment, which in turn lead to increased operating temperatures. The higher the required speeds and levels of precision are for the bearing, the more these faults become evident. The average roughness  $R_a$  of the bearing seats must be complied with in order to ensure that the corresponding fit only varies very slightly in case of installation (smoothing of surfaces).

# 17. Installation

## 17.1. Preparation of installation

Super precision bearings fulfill the stringent requirements on cleanliness and precision. The bearings should be installed with the utmost care. Make sure that they are installed in a room that is as clean as possible and free of dust with regulated temperature. Prior to installing the bearings, the dimensional accuracy of the connecting parts must be checked. Only provide and use tools that are suited for installation. Only open the bearing packages right before the installation. Remove excessive anti-corrosion oil with the aid of a clean lint-free cloth. In case of multiple bearings, the inner rings cannot be interchanged.

## 17.2. Greasing of bearings

In case of greasing and incompatibility of the anti-corrosion oil with the provided grease, the bearings are to be washed using a low-viscosity oil or kerosene and dry. Afterwards, apply the recommended amount of grease evenly to the outer and/or inner contour of the cage between the rollers, use your fingers to spread the grease on the rollers while manually turning them. (The information on recommended amount of grease can be found in Section 23.2.3. Amount of grease).

## 17.3. Bearing installation

The cylindrical roller bearings with tapered bore have a greater bearing clearance compared to those with a cylindrical bore. The tapered inner rings are secured to the shaft taper by means of clamping nuts. Depending on how much they are displaced axially, the inner ring expands and the bearing can be installed with play, without play or even with pretensioning.

# 17. Installation

## Adjustment using envelop circle measuring device

To this end, the outer ring (series NN or N) is first installed in the housing and the race diameter is calculated. Subsequently, the outer envelop circle diameter of the cylindrical rollers are measured at the pretensioned inner ring with roller race. The difference between the race diameter and the envelop circle diameter results in the current bearing play and / or pretensioning. The desired parameters can be adjusted by further axial displacement.

The relevant dimension L must be calculated in order to be able to fix the bearing in this position with an adapter ring. For this purpose, the distance between the bearing's inner ring and shaft shoulder is measured at four measuring points staggered by 90°. After removing the inner ring, the smoothed adapter ring is slid onto the cylindrical part of the shaft between the shaft shoulder and inner ring. The inner ring is finally secured by means of a clamping nut.

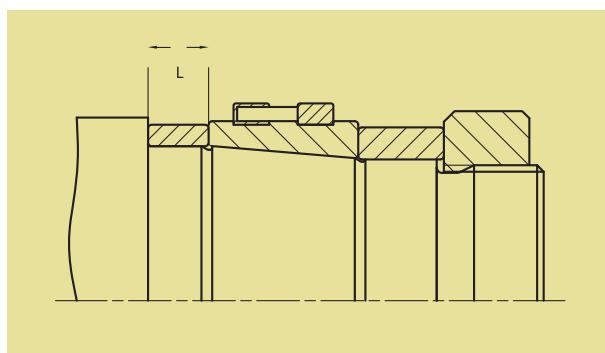

Fig. 17.1. Adjustment with envelop circle measuring device

## Adjustment without envelop circle measuring device

Install the outer ring in the housing. Arbitrarily tension the inner ring with the roller race on the shaft taper and align it precisely in the housing. Measure the radial play by radially sliding the inner ring to the outer ring. Allow for the desired radial play or pretensioning by axially shifting the inner ring. In case of taper 1:12, the sliding distance with solid shafts is approx. 20 times greater than the resulting radial expansion. Secure the bearing with an adapter ring in line with the adjustment using the envelop circle measuring device.

The set radial play or pretensioning influences the attainable speed as follows:

Single-row cylindrical roller bearings	
Radial play / pretensioning	Attainable speed
Pretensioning -5 bis 0 $\mu\text{m}$	<0,75 * n( grease )
0 $\mu\text{m}$ , free of play	0,75 to 1 * n( grease )
Radial play 0 to 5 $\mu\text{m}$	1 to 1,1 * n( grease )
Radial play 0 to 5 $\mu\text{m}$	1 * n(oil)

Double-row cylindrical roller bearings	
Radial play / pretensioning	Attainable speed
Pretensioning -5 bis 0 $\mu\text{m}$	<0,5 * n(grease)
Radial play 0 to $2 \cdot 10^{-5} \cdot dm$ (mm)	0,5 bis 0,75 * n(grease)
Radial play $2 \cdot 10^{-5} \cdot dm$ to $4 \cdot 10^{-5} \cdot dm$ (mm)	0,75 bis 1 * n(grease)
Radial play $0 to 1 \cdot 10^{-5} \cdot dm$ (mm)	1 * n(oil)
Average bearing diameter $dm = (d+D)/2$

### 20.2 High-precision cylindrical roller bearings, double-row

# 21. Terms and symbols according to DIN ISO 1132-1, DIN 620

## 21.1. Bore diameter

$d$	Nominal diameter of bore
$d_s$	Individual bore diameter
$d_{sp}$	Individual bore diameter in single plane
$\Delta_{ds}$	Deviation of individual bore diameter, difference between an individual bore diameter and the nominal diameter of the bore, $\Delta_{ds} = d_s - d$
$V_{ds}$	Variation in bore diameter, difference between the largest and smallest individual bore diameter of an individual ring, $V_{ds} = d_{smax} - d_{smin}$
$d_m$	Average bore diameter, arithmetic mean of the largest and smallest of the individual bore diameters of an individual ring, $d_m = (d_{smax} + d_{smin}) / 2$
$\Delta_{dm}$	Deviation of average bore diameter, difference between the average bore diameter and the nominal diameter of the bore, $\Delta_{dm} = d_m - d$
$d_{mp}$	Average bore diameter in a single plane, arithmetic mean of the largest and smallest individual bore diameter determinable in a radial plane, $d_{mp} = (d_{smax} + d_{smin}) / 2$
$\Delta_{dmp}$	Deviation of average bore diameter in a single plane, difference between the average bore diameter and the nominal diameter in a radial plane, $\Delta_{dmp} = d_{mp} - d$
$V_{dp}$	Variation of individual bore diameter in a single plane, difference between the largest and smallest bore diameter determinable in a radial plane, $V_{dp} = d_{smax} - d_{smin}$
$V_{dmp}$	Variation of medium bore diameter, difference between the largest and smallest medium bore diameter determinable in individual radial planes respectively at an individual ring, $V_{dmp} = d_{mpmax} - d_{mpmin}$
$V_{dp}/2$	Roundness of a level

## 21.2. Shell diameter

$D$	Nominal diameter of shell (outer diameter)
$D_s$	Individual shell diameter
$D_{sp}$	Individual shell diameter in a single plane
$\Delta_{Ds}$	Deviation of individual shell diameter, difference between an individual shell diameter and the nominal diameter of the shell, $\Delta_{Ds} = D_s - D$
$V_{Ds}$	Variation of shell diameter, difference between the largest and smallest individual shell diameter of an individual ring, $V_{Ds} = D_{smax} - D_{smin}$
$D_m$	Average shell diameter, arithmetic mean of the largest and smallest individual shell diameter of an individual ring, $D_m = (D_{smax} + D_{smin}) / 2$
$\Delta_{Dm}$	Deviation of average shell diameter, difference between the average shell diameter and the nominal diameter of the shell, $\Delta_{Dm} = D_m - D$
$D_{mp}$	Average shell diameter in a single plane, arithmetic mean of the largest and smallest individual shell diameter determinable in a radial plane, $D_{mp} = (D_{smax} + D_{smin}) / 2$
$\Delta_{Dmp}$	Deviation of average shell diameter in a single plane, difference between the average shell diameter and the nominal diameter of the shell in an individual radial plane, $\Delta_{Dmp} = D_{mp} - D$
$V_{Dp}$	Variation of individual shell diameter in a single plane, difference between the largest and smallest individual shell diameter determinable in an individual radial plane, $V_{Dp} = D_{smax} - D_{smin}$
$V_{Dmp}$	Variation of average shell diameter, difference between the largest and smallest average shell diameter determinable in individual radial planes respectively at an individual ring, $V_{Dmp} = D_{mpmax} - D_{mpmin}$
$V_{Dp}/2$	Roundness of a level

# 21. Terms and symbols according to DIN ISO 1132-1, DIN 620

## 21.3. Width

B	Nominal width of inner ring
C	Nominal width of outer ring
$B_s$	Individual inner ring width
$C_s$	Individual outer ring width
$\Delta B_s$	Deviation of individual inner ring width, difference between an individual inner ring width and the nominal width of the inner ring, $\Delta B_s = B_s - B$
$\Delta C_s$	Deviation of individual outer ring width, difference between an individual outer ring width and the nominal width of the outer ring, $\Delta C_s = C_s - C$
$V_{B_s}$	Variation of inner ring width, difference between the largest and smallest actual individual ring width of an individual inner ring, $V_{B_s} = B_{smax} - B_{smin}$
$V_{C_s}$	Variation of outer ring width, difference between the largest and smallest actual individual ring width of an individual outer ring, $V_{C_s} = C_{smax} - C_{smin}$
$B_m$	Average inner ring width, arithmetic mean of the largest and smallest individual ring width determinable at an outer ring, $B_m = (B_{smax} + B_{smin}) / 2$
$C_m$	Average outer ring width, arithmetic mean of the largest and smallest individual ring width determinable at an outer ring, $C_m = (C_{smax} + C_{smin}) / 2$

## 21.4. Corner radius

	Nominal chamfer dimensions
$r_s$	Individual chamfer dimensions
$r_{smin}$	Smallest individual chamfer dimensions , smallest permissible and individual radial and axial chamfer dimensions of a ring
$r_{smax}$	Largest individual chamfer dimensions , largest permissible and individual radial and axial chamfer dimensions of a ring

## 21.5. Variation in wall thickness

$K_i$	Variation in wall thickness between inner ring/race and bore, difference between the largest and smallest radial distance between the bore surface and the race on the outside of the inner ring, in middle of race
$K_e$	Variation in wall thickness between outer ring/race and outer ring/shell, difference between the largest and smallest radial distance between the shell surface and the race on the inside of the outer ring, in middle of race

## 21. Terms and symbols according to DIN ISO 1132-1, DIN 620

### 21.6. Running accuracy

#### 21.6.1. Radial run-out

- ia Radial run-out of the inner ring at the assembled bearing, difference between the largest and smallest radial distance between the bore surface of the inner ring, with different angle position of the inner ring, and a fixed point relating to the outer ring
- ea Radial run-out of the outer ring at the assembled bearing, difference between the largest and smallest radial distance between the shell surface of the outer ring, with different angle position of the outer ring, and a fixed point relating to the inner ring

#### 21.6.2. Axial run-out

- $s_{ia}$  Axial run-out of the inner ring at the assembled bearing, difference between the largest and smallest axial distance between the reference side surface of the inner ring, with different angle positions of the inner ring, at a radial distance from the inner ring axis equal to half of the race diameter of the inner ring and at a fixed point relating to the outer ring
- $s_{ea}$  Axial run-out of the outer ring at the assembled bearing, difference between the largest and smallest axial distance between the reference side surface of the outer ring, with different angle positions of the outer ring, at a radial distance from the outer ring axis equal to half of the race diameter of the outer ring and at a fixed point relating to the inner ring

#### 21.6.3. Lateral run-out

- $s_d$  Axial run-out of the inner ring lateral surface to the bore (lateral run-out)
- $s_D$  Variation in slope of the shell line to the reference side surface (lateral run-out)

# 22. Lubrication

## 22.1. General

Both grease and oil may be used as lubricants. The lubricant is a load-bearing element that separates the rolling elements and sliding elements from one another.

That's why it is necessary to ensure that lubricant is applied at all points of contact. In case of continuous lubrication, it also assumes the role of cooling at the same time. The choice of lubrication approach depends on the different operating conditions, such as speeds, temperatures and loads.

## 22.2.1. Grease service life

A grease's effectiveness deteriorates during operation and thus has a corresponding impact of the bearing's operation. That's why the grease service life is regarded as a key factor for the fatigue life of bearings.

$k_f$  1 for N10 and N19

$k_f$  2 for NN30 and NNU49

$k_f$  0,75 for spindle bearings with contact angle 15°

$k_f$  0,9 for spindle bearings with contact angle 25°

$n$  Speed

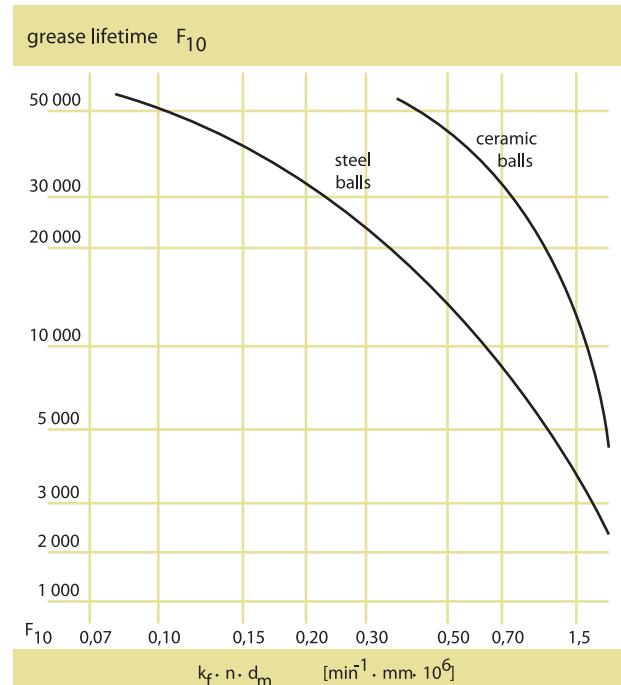

$d_m$  medium bearing diameter  $(D+d)/2$

## 22.2. Grease lubrication

Grease is normally used as lubricant if extremely high speeds are not to be expected. Advantages of grease include:

- Less complex design
- Less system complexity
- Possibly of lifetime lubrication
- Compact size for lubrication equipment and seals
- Environmentally friendly

Thanks to the constant advances and innovations made in lubricating greases, it has been possible to increase bearing speeds considerably. Greased and sealed bearings also offer the advantage of ensuring maximum cleanliness, since the interior of the bearing is protected against dirt.

## 22. Lubrication

### 22.2.2. Running-in of grease

The performance of the bearings and thus their service life is influenced in a positive manner due to the careful commissioning of greased bearings. Running-in is recommended, which consists of running time and down time.

This ensures both a uniform distribution of the lubricating grease and prevents bearings from overheating during operation. For higher speeds, the running-in process should be implemented first at 50% and then at 0.75 times the expected rotational speed. The necessary number of running-in processes may vary depending on the size and number of bearings as well as maximum speed and bearing environment.

In general, we recommend the following start/stop cycle:

Speed	Run-time	time	Repe-tition	Total time
0,5 * $n_{\max}$	20 s	2 min	5x	11 min 40 s
0,75 * $n_{\max}$	20 s	2 min	5x	11 min 40 s
$n_{\max}$	20 s	2 min	5x	11 min 40 s
$n_{\max}$	30 s	2 min	10x	25 min
$n_{\max}$	1 min	1 min	10x	20 min

If the steady-state temperature is still not achieved, additional cycles are implemented with longer running periods and shorter downtimes.

## 22. Lubrication

### 22.2.3. Amount of grease

The amount of grease complies with the normal fill quantity N of the spindle bearing and refer to approx. 50% of the trouble-free interior of the bearing.

### 22.2.4. Running-in of grease

If the operating speed and temperature are greater than those permitted for lubricating grease, oil lubrication should be used. Viable lubrication methods include oil/mist or oil/air lubrication. Both types of lubrication methods ensure a minimum volume lubrication and thus the minimum friction losses. Greater quantities of oil used for cooling lubrication allow for a greater dissipation of heat from the bearing but also increase the bearing's performance loss at the same time. The lubricating oil must have sufficient viscosity in order to be able to provide a load-bearing lubricating film at the bearing's rolling surfaces and sliding surfaces. That said, the viscosity of the oil at operating temperature is decisive. The viscosity must be lower when the rotational speed is greater. The lubricating oil shall be selected according to the nominal viscosity at a reference temperature of 40 °C. Oils having a nominal viscosity of 68 mm<sup>2</sup>/s are suitable, whereas the standard approach nowadays is the oil/air lubrication method. The oils used must have a purity class of 13/10 as in accordance with ISO 4406. Typical oil quantities include depending on injection rate at 3, 5, 10, 30, 60 and 100 mm<sup>3</sup> and 6 to 10 injection rates per hour.

## 23. Terms of delivery ..... Outside Germany

### Terms of delivery

General terms and conditions are individually stipulated between Das Lager Deutschland GmbH WÄLZLAGERFABRIK and its customers.

No responsibility is accepted for the accuracy of this information.  
Changes due to technical improvements can be made without any advance notice.
